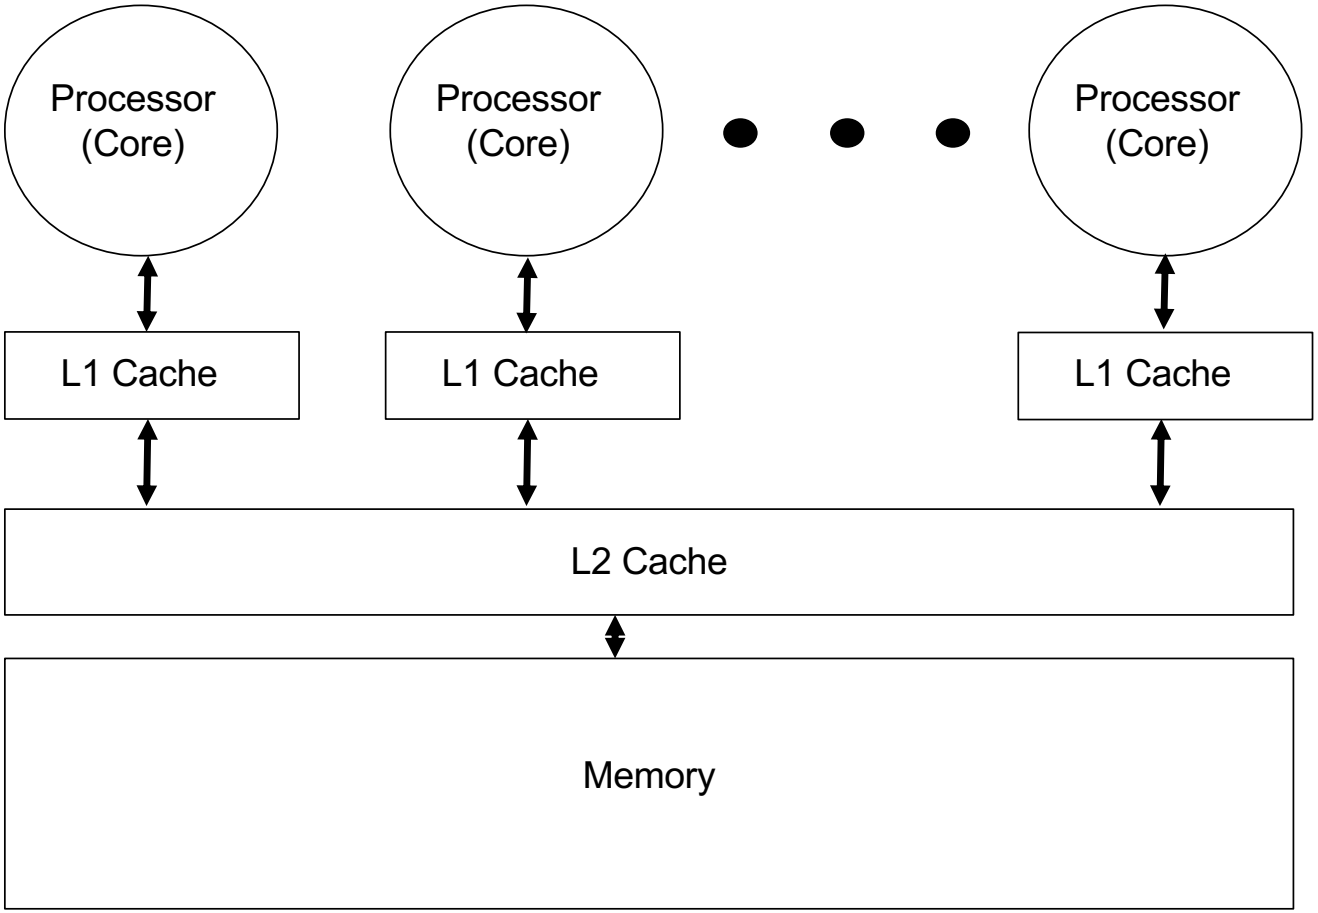
Lecture 6

Chip multiprocessors

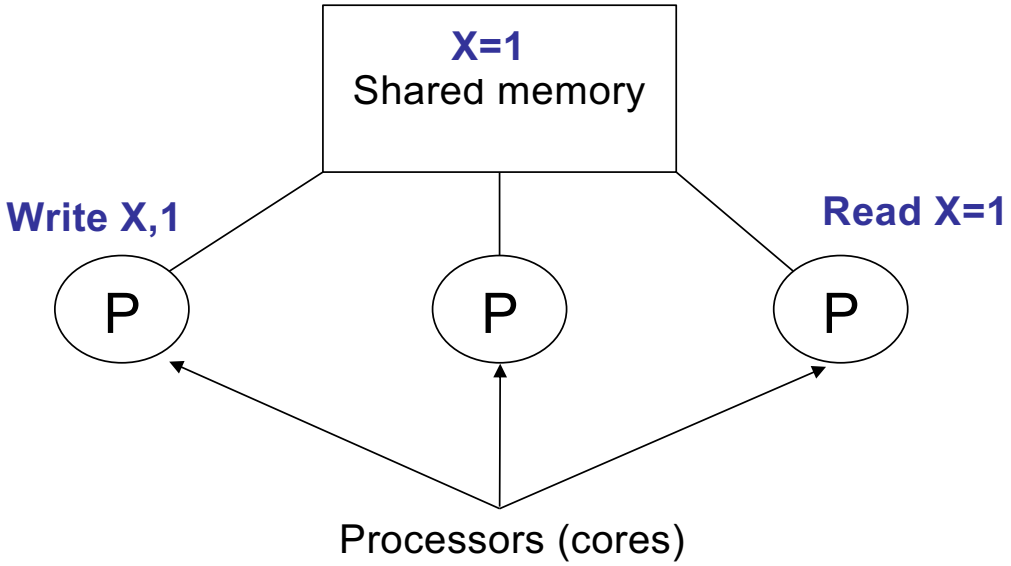
- **Multithreading techniques (Sections 5.2.1, 8.3)**
  - ✓Interleaved (fine-grain) multithreading
  - ✓Block (coarse-grain) multithreading
  - ✓Simultaneous multithreading
- **Cache coherence solutions (Sections 5.4.1-5.4.3)**

Multicore Programming Model

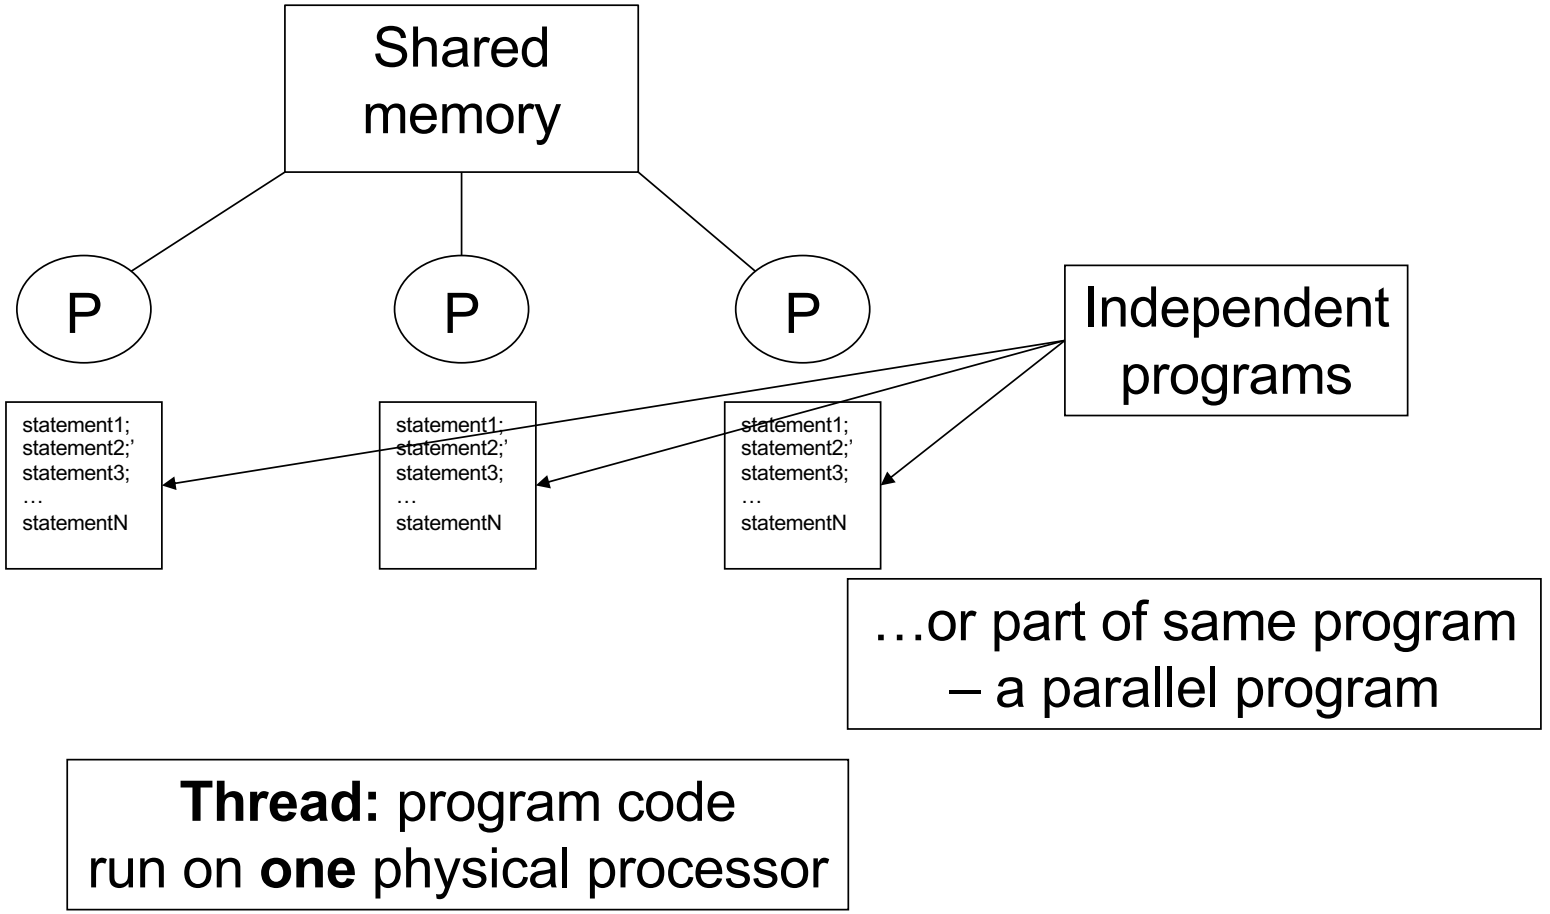
Architecture Model of a Multicore System



Programming Model of a Multicore System



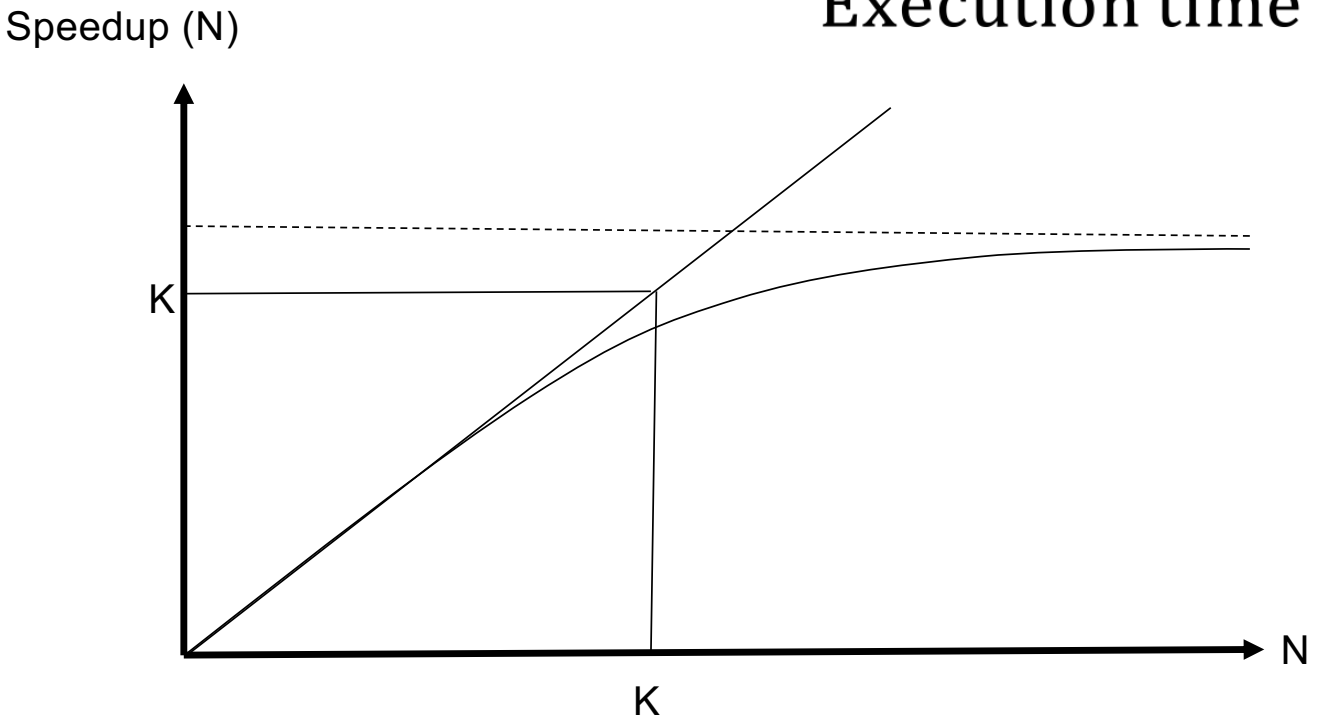
Thread-Level Parallelism



Thread: program code run on **one** physical processor

Goal: Parallel Execution

$$\text{Speedup (N)} = \frac{\text{Execution time 1 thread}}{\text{Execution time N threads}}$$



SP < 1/f

- f – fraction of serial code
- See Amdahl's Law

Discussion:
What are the sources for sub-linear speedup?

Question:
Assume that 90% of a sequential program can be parallelized.

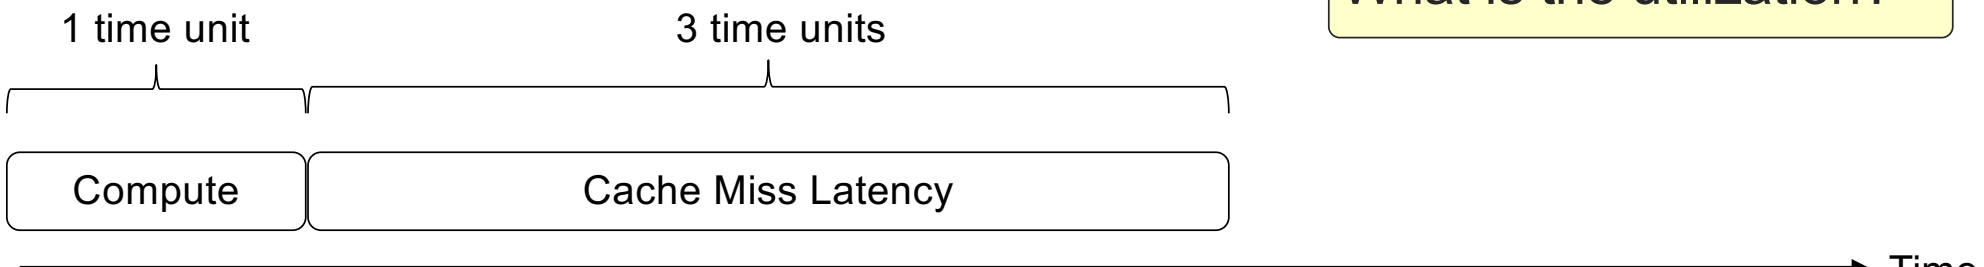
What is the maximum speedup we can get?

Answer:
According to Amdahl's Law:
$SP = 1/(f - (1-f)/P)$
Hence, $SP<1/f = 1/(1-0.90) = 10$

Multithreading
(Sections 5.2.1, 8.3)

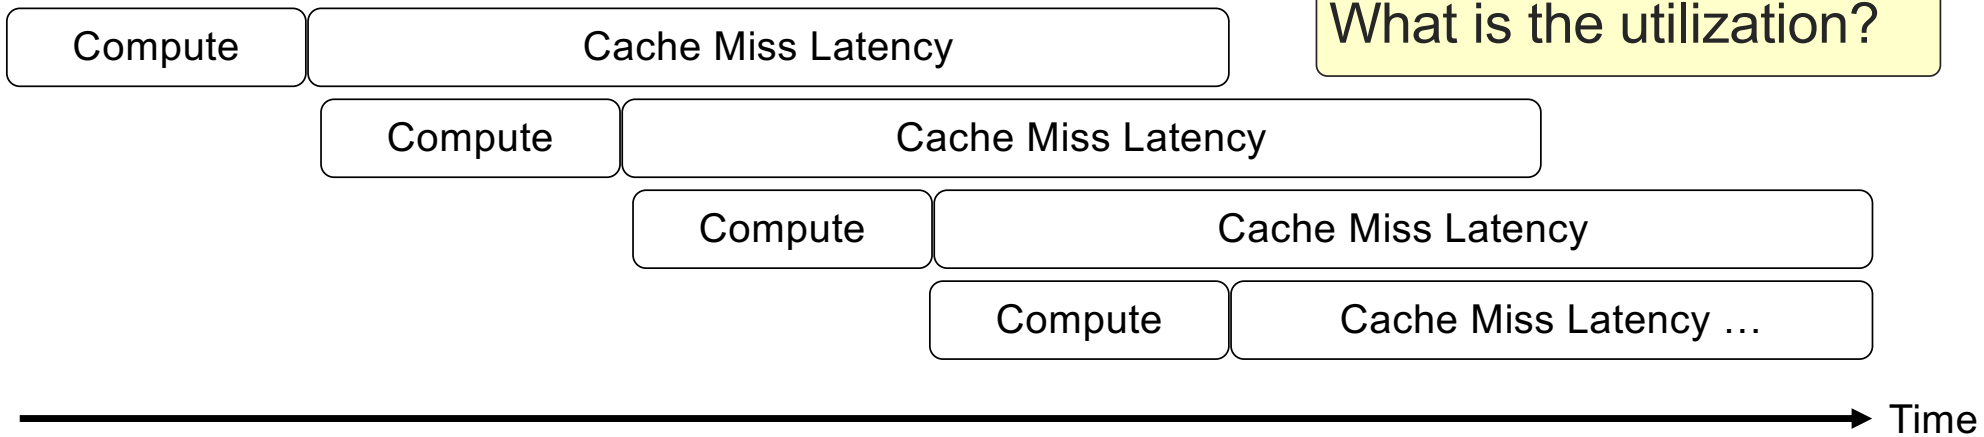
Motivation

Question:
What is the utilization?



Utilization: 25%!

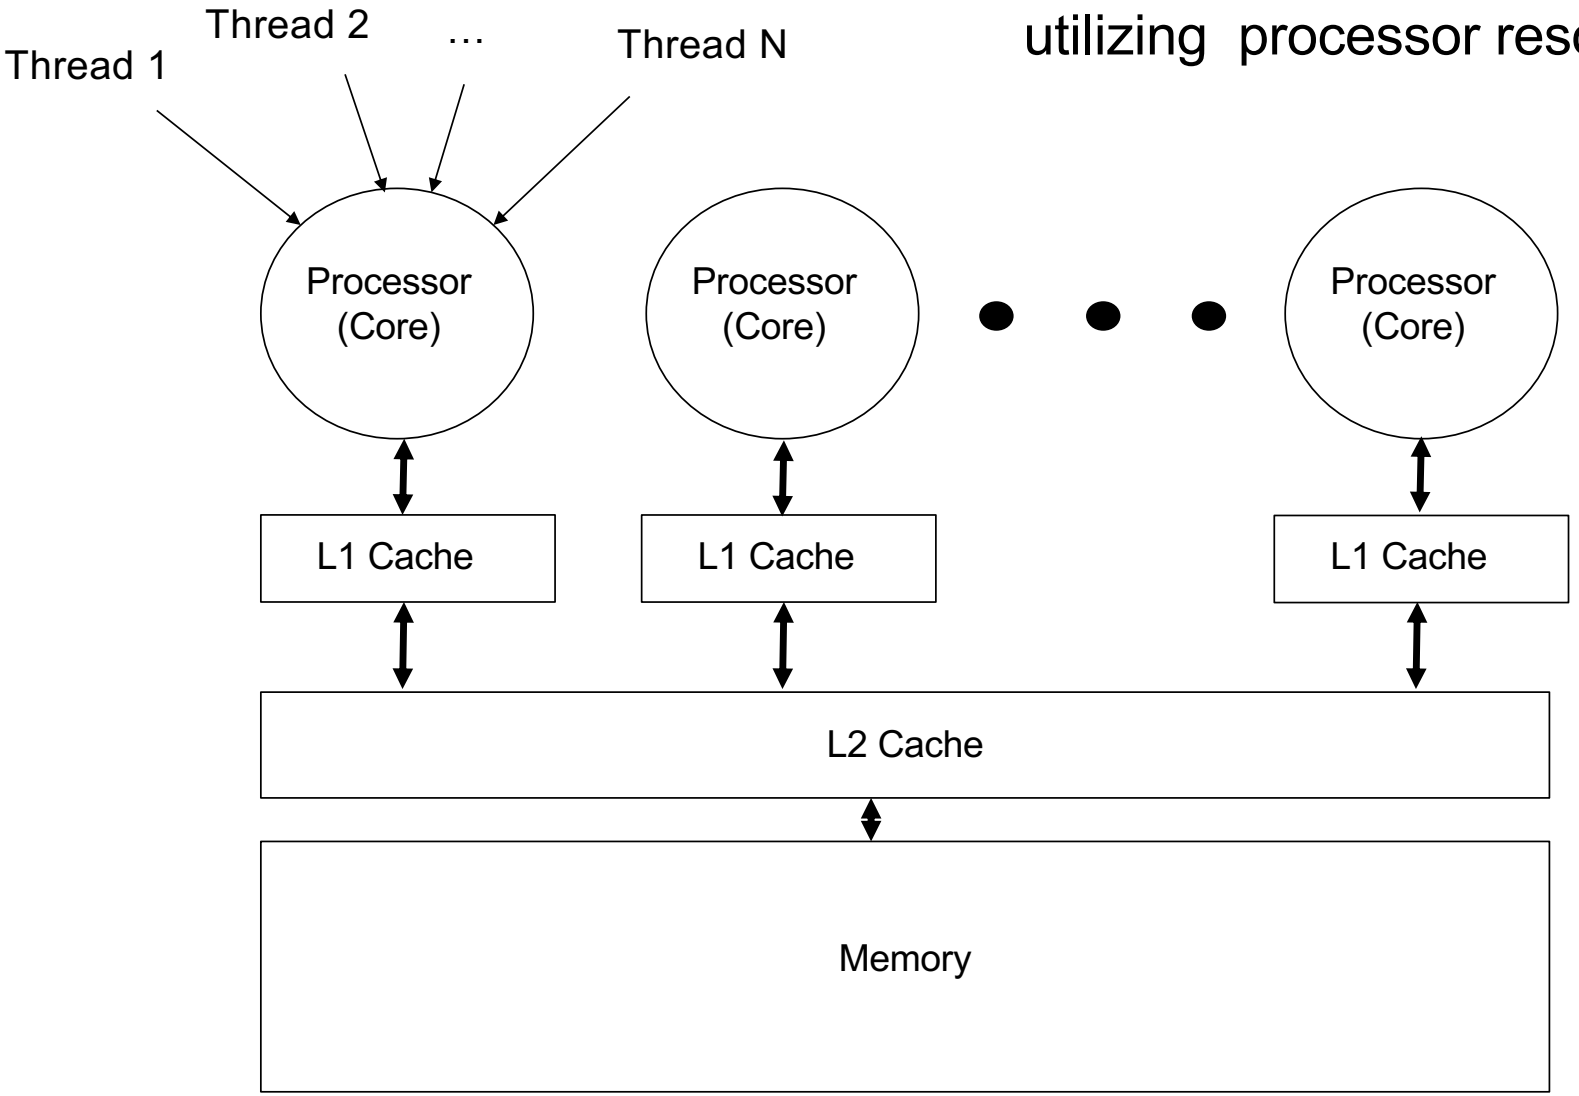
Question:
What is the utilization?

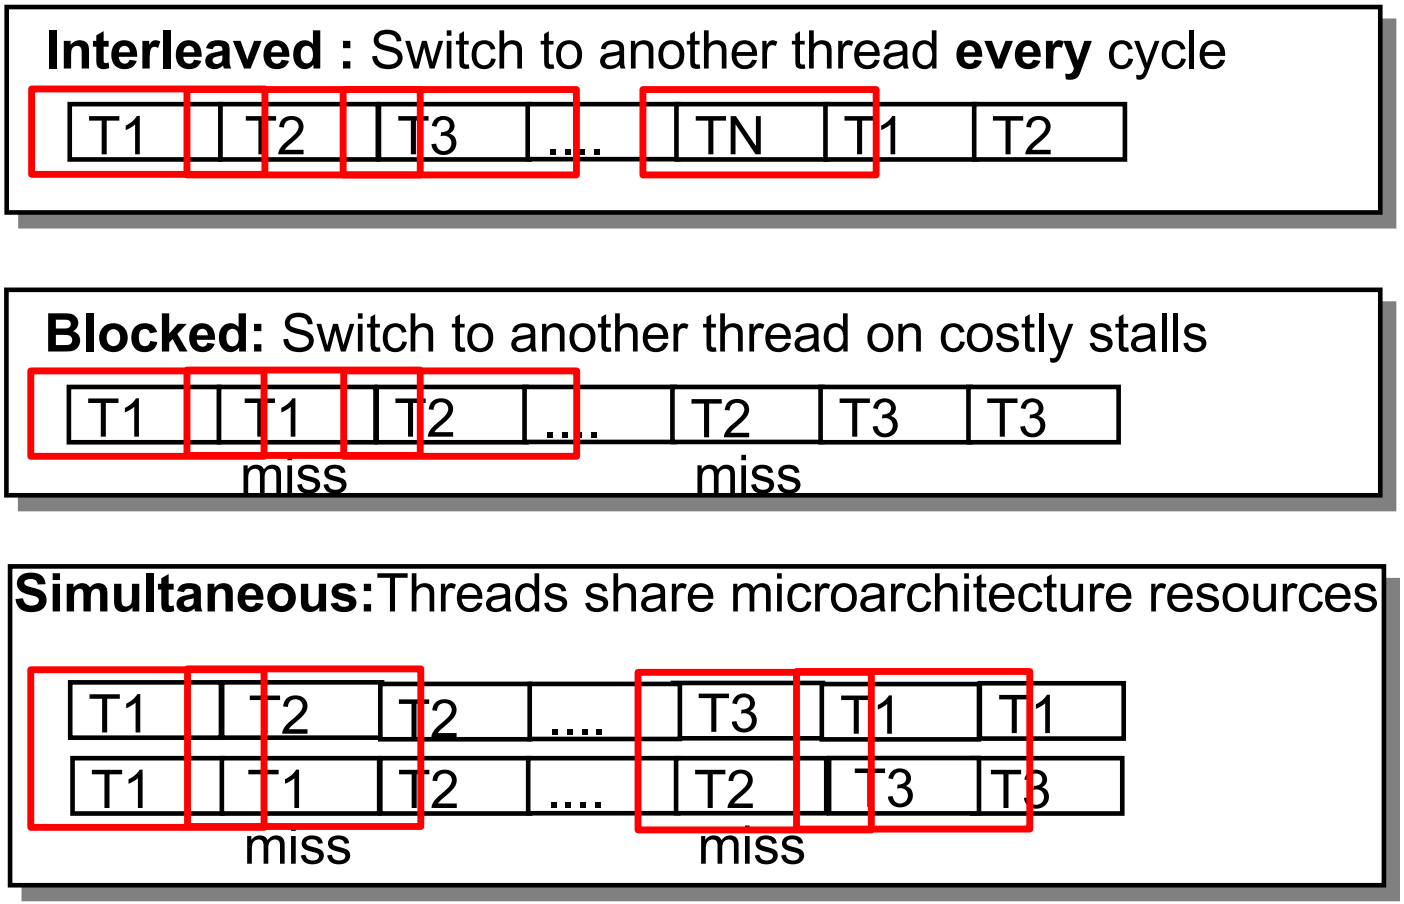


Four programs (threads) could overlap the latency

Utilization: 100%!

Multi-threading aims at utilizing processor resources better





Interleaved : Switch to another thread **every** cycle
T1
T2
T3
....
TN
T1
T2
Blocked: Switch to another thread on costly stalls

Interleaved Multithreading

Blocked Multithreading

Simultaneous Multithreading

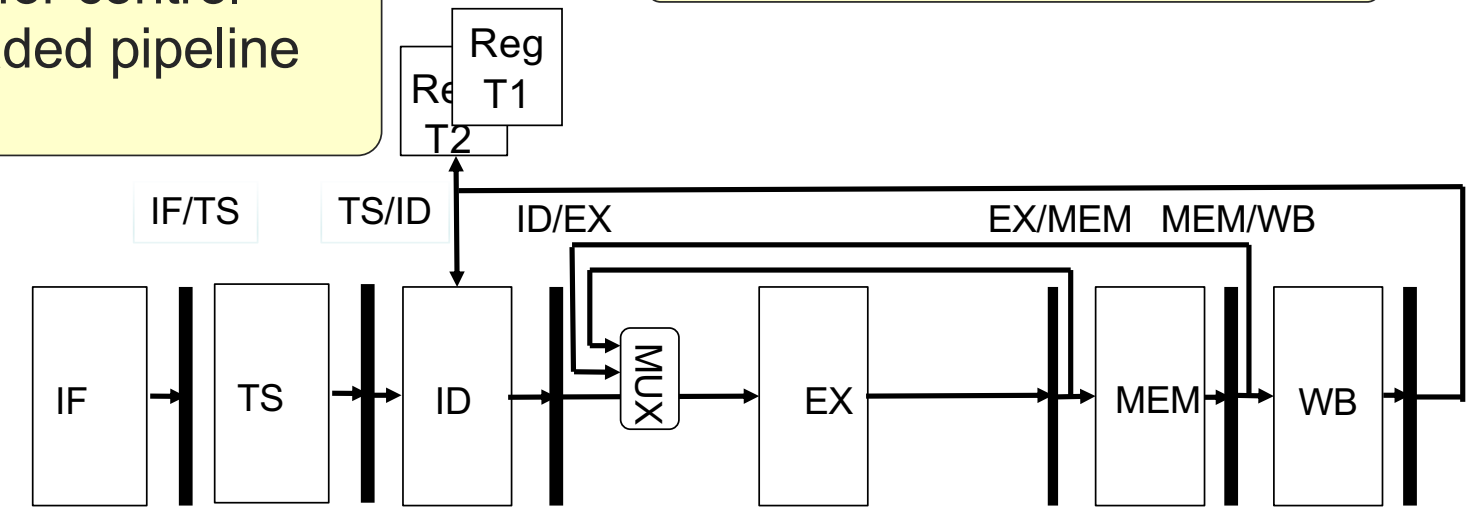
Hazards have less impact. Can hide long latencies

Question:
How many threads are needed to eliminate the cycles lost for control hazards in the multithreaded pipeline below?

Answer:
Four threads

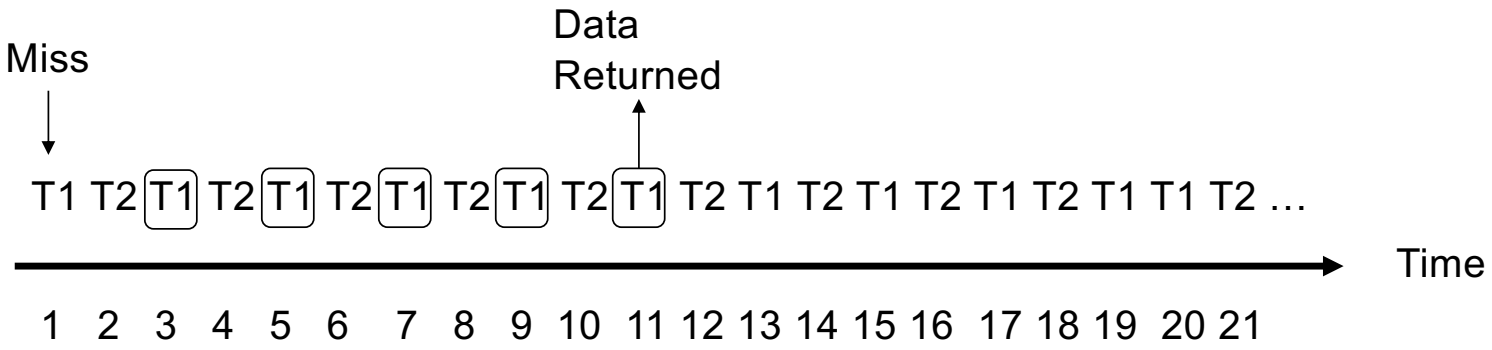


UNUSED UNUSED UNUSED BNEZ R1, LOOP

T4 T3 T2 T1: BNEZ R1, LOOP

Question:
How many cycles are unused if T1 experiences a cache miss that takes 10 cycles to serve?

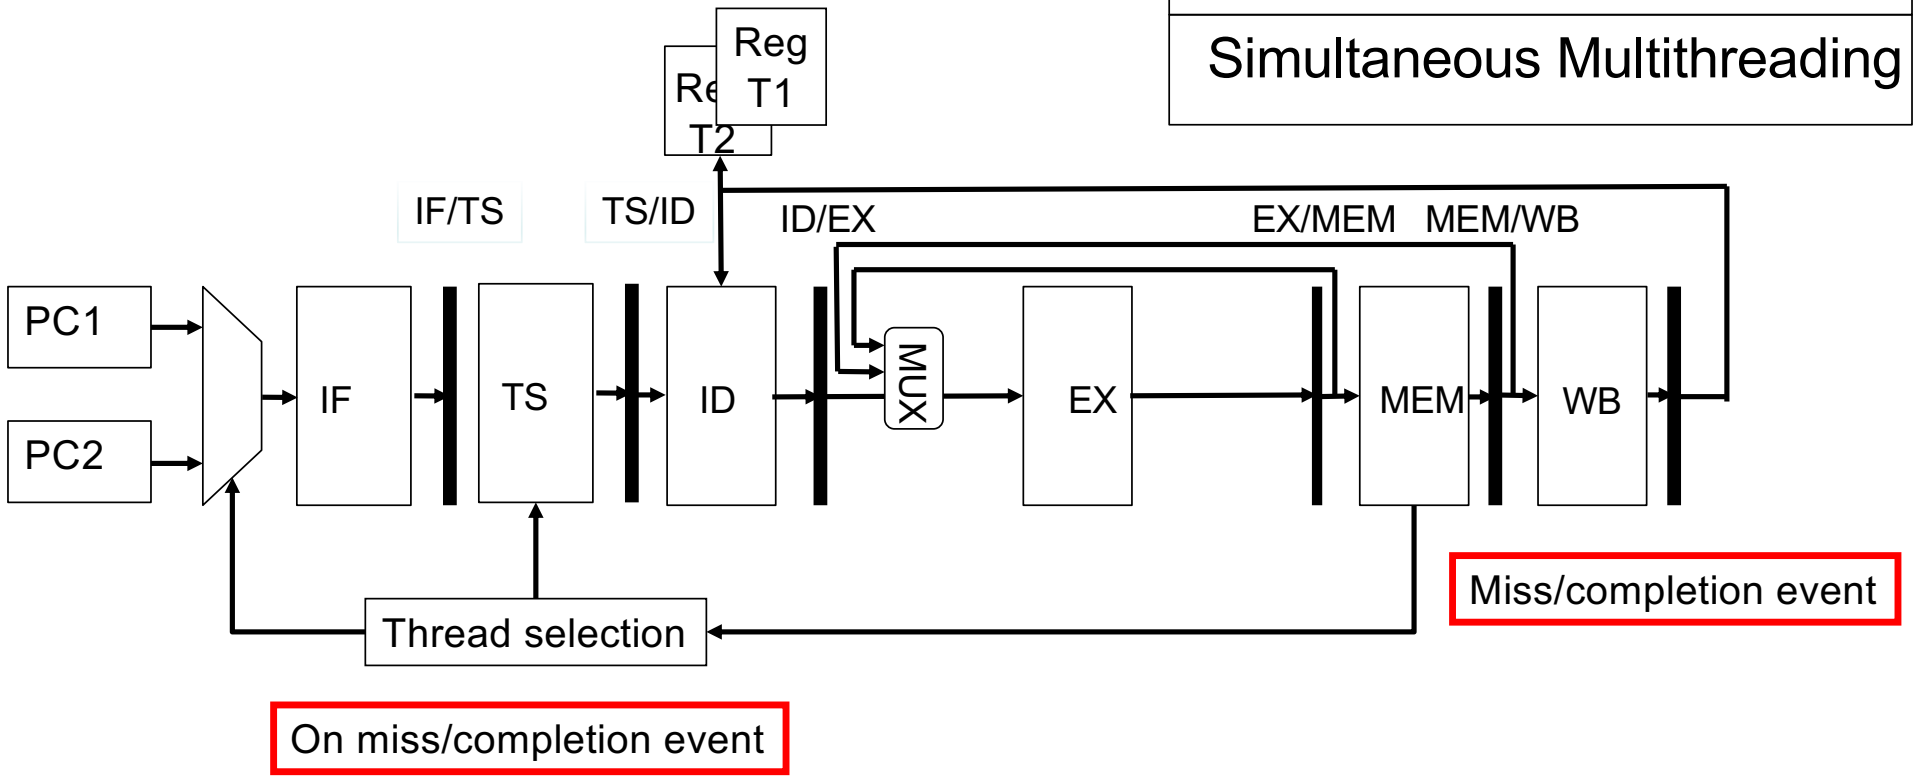
Answer:
5 cycles are unused. T2 can make use of half of the cycles.



Interleaved Multithreading

Blocked Multithreading

Simultaneous Multithreading

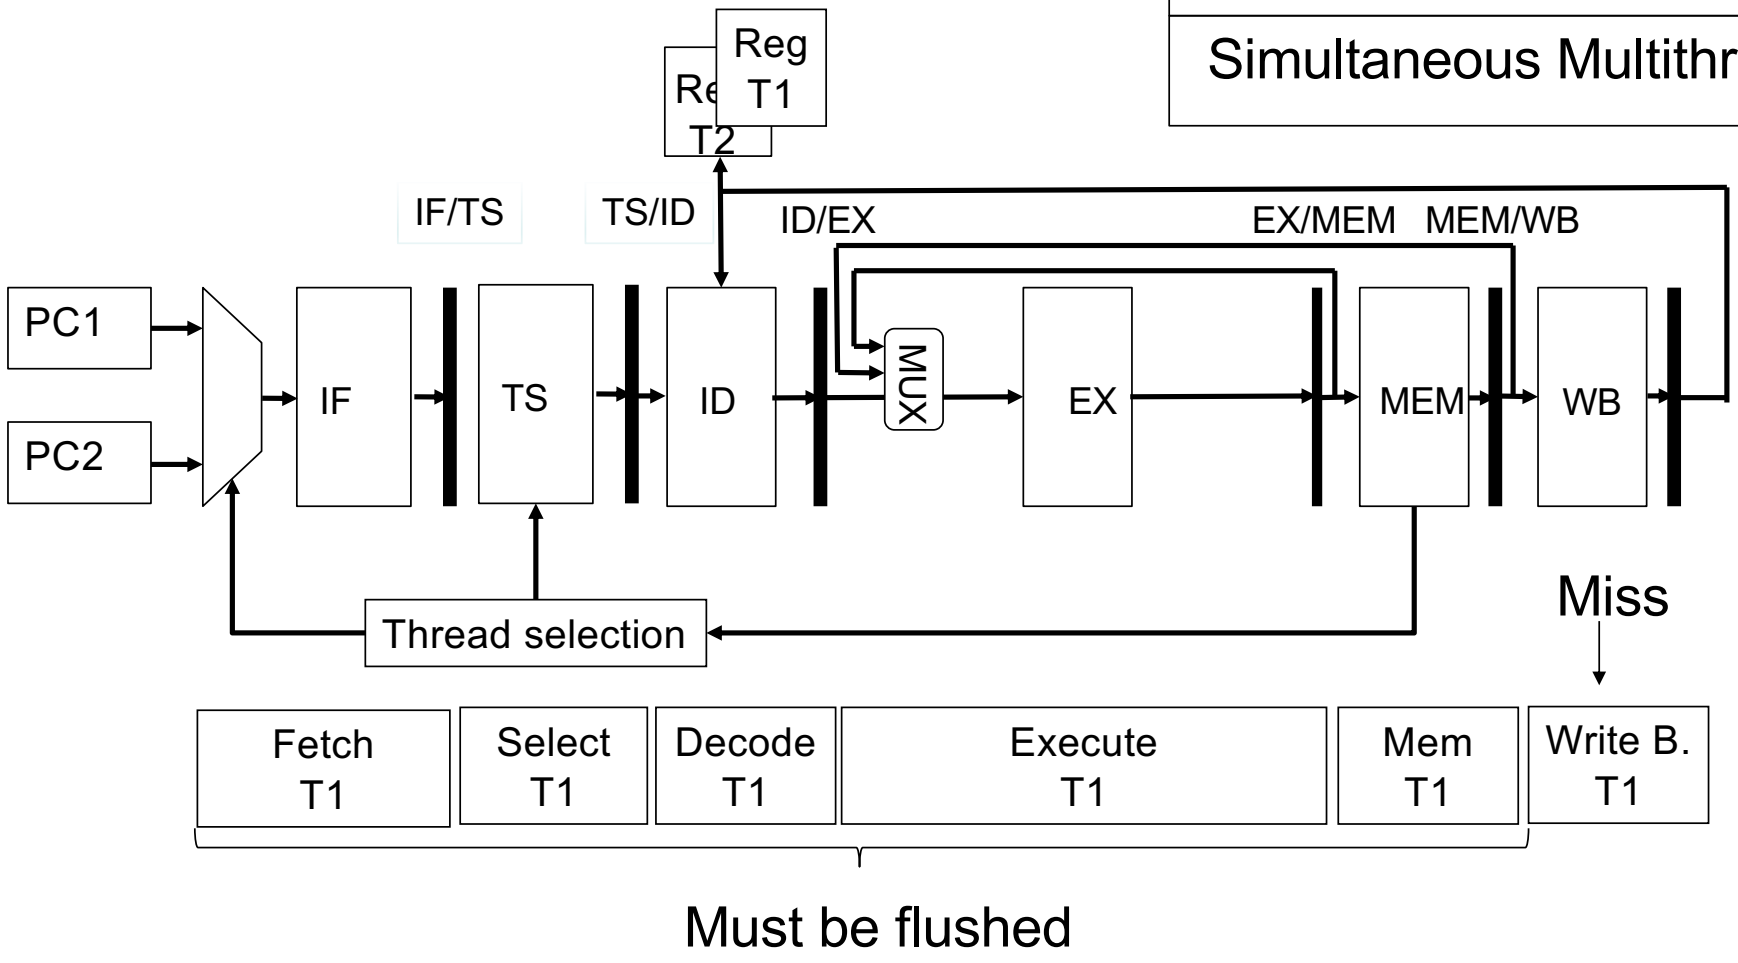


Cycle X

Interleaved Multithreading

Blocked Multithreading

Simultaneous Multithreading

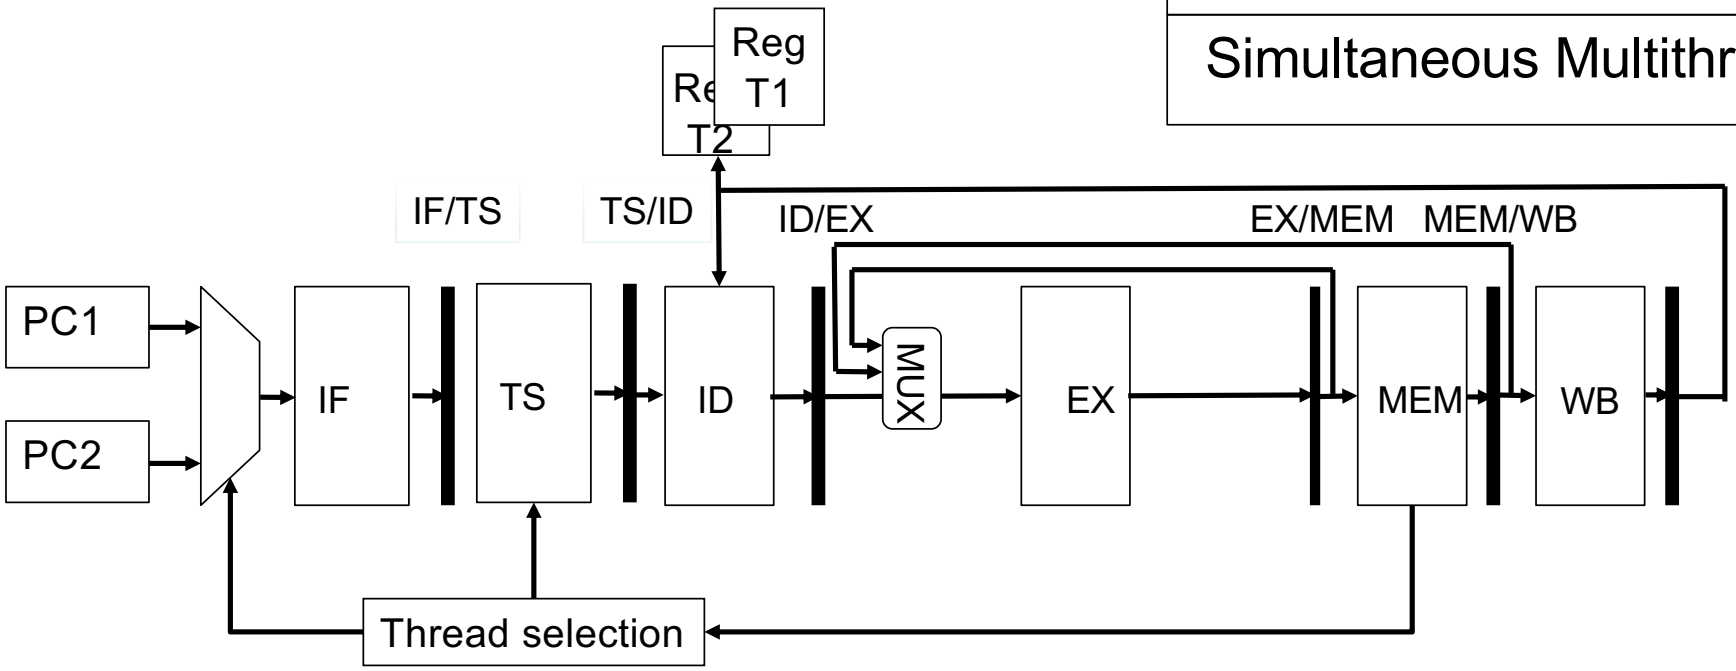


Cycle X + 1

Interleaved Multithreading

Blocked Multithreading

Simultaneous Multithreading



Fetch T2	Unused	Unused	Unused	Unused	Unused

Only effective for long-latency operations

Significant overhead in deep out-of-order pipelines

Interleaved Multithreading

Blocked Multithreading

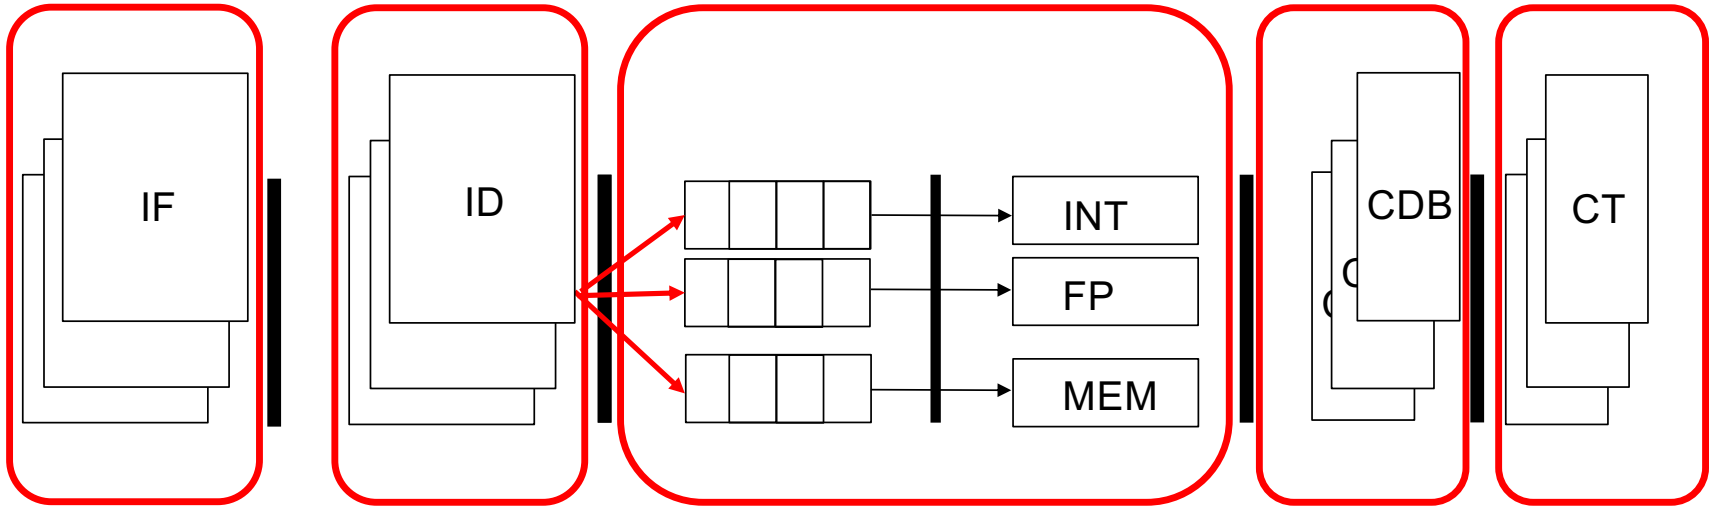
Blocked Multithreading

Simultaneous Multithreading



Cache Coherence Solutions
(Sections 5.4.1-5.4.3)

Latest Write to a Location: Single Processor

Notation:

- Processor *i* reads from location X: $R_i(X)$
- Processor *i* writes a value Y to location X: $W_i(X)$=Y

Example: Consider the following sequence of reads and writes to location X:

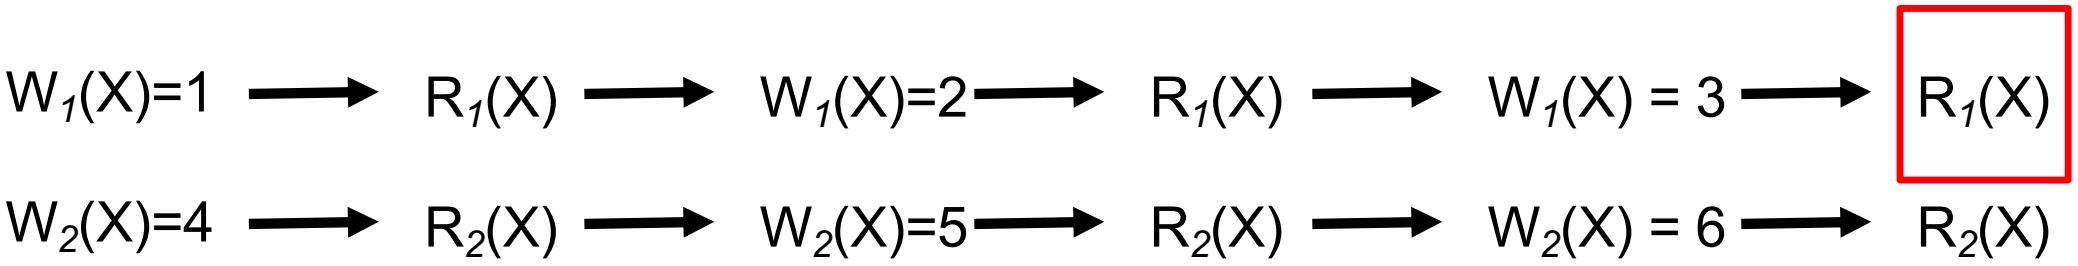
$W_i(X)=1 \rightarrow R_i(X) \rightarrow W_i(X)=2 \rightarrow R_i(X) \rightarrow W_i(X) = 3 \rightarrow R_i(X)$

Question:
What value is returned by the last read request?

Answer:
The returned value is 3 because it is reflected **by the latest write** to location X.

Latest Write to a Location: Two Processors

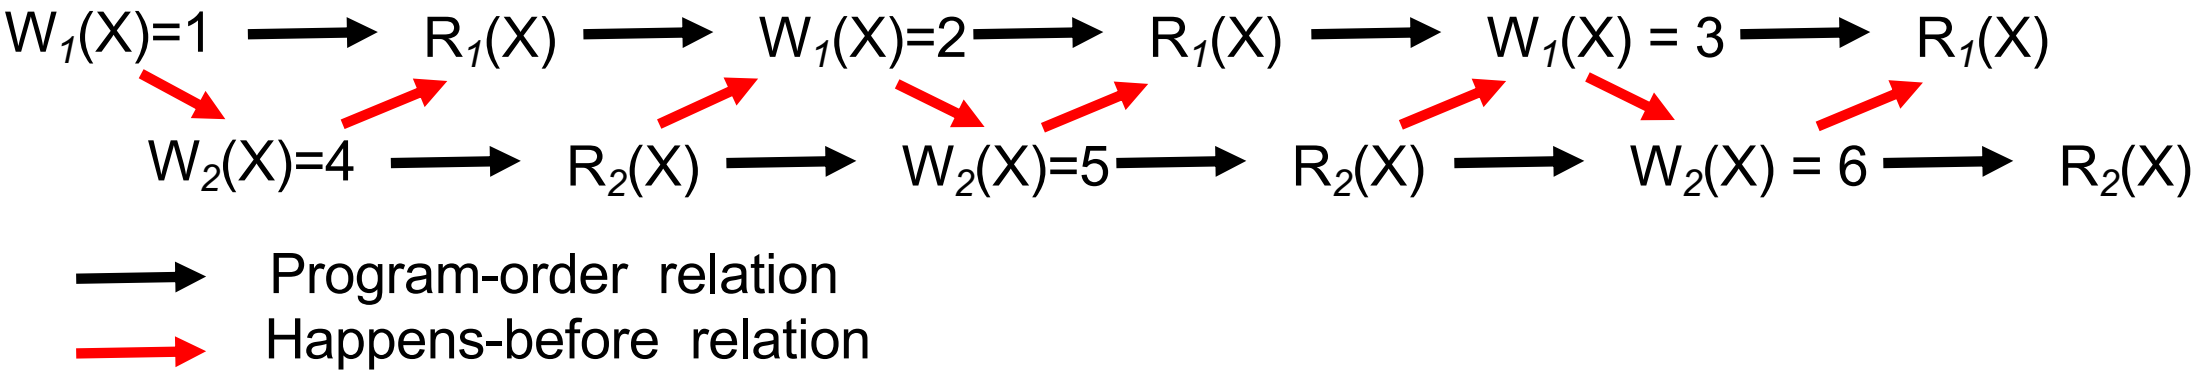
Example: Consider the following sequence of reads and writes to location X from two processors 1 and 2:



Question:
What value is returned by the last read request from processor 1?

Answer:
It all depends on the order by which writes arrive at memory!

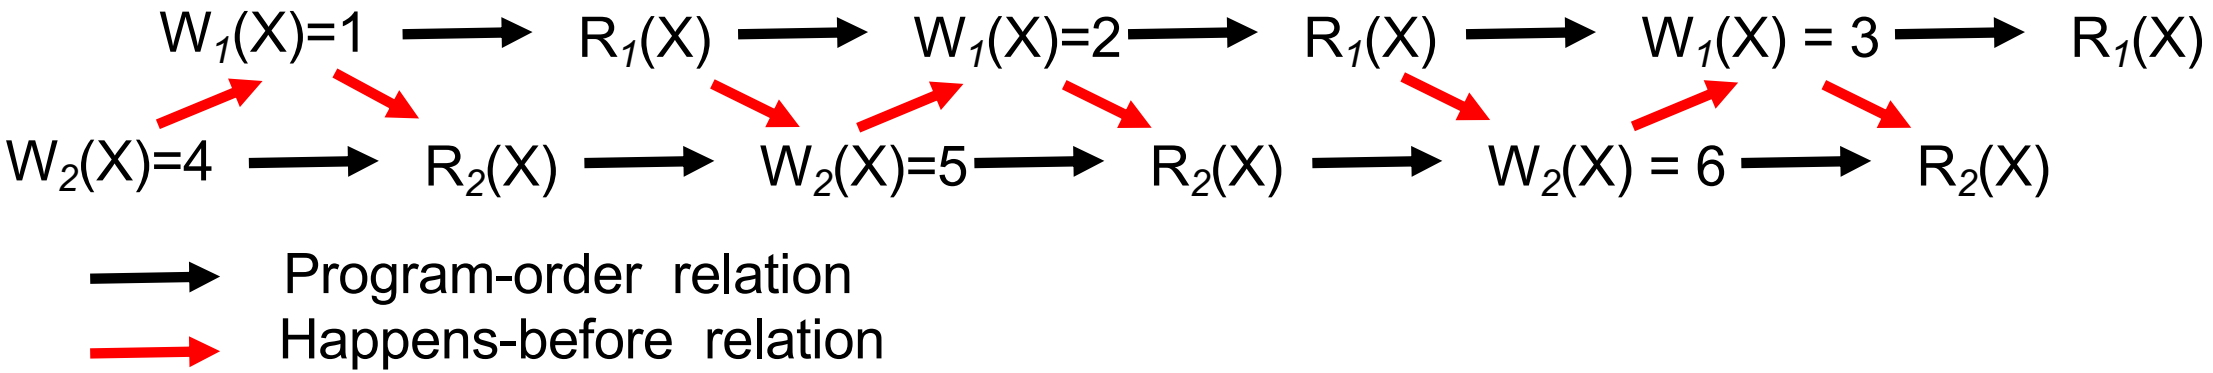
Latest Write to a Location: Two Processors – One Scenario



Question:
What value is returned by the last read request from processor 1?

Answer:
Now it's unambiguously 6 because the last write from Processor 2 is the last write.

Latest Write to a Location: Two Processors – Another Scenario

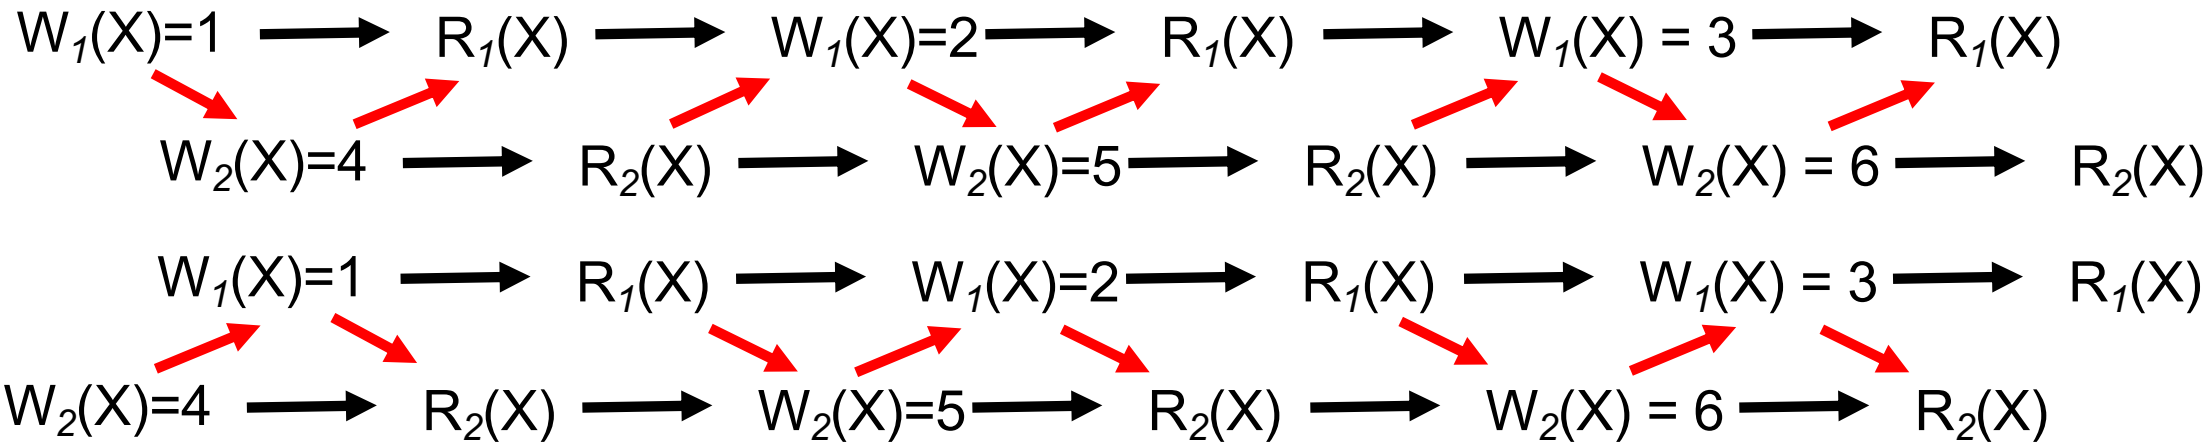


Question:
What value is returned by the last read request from processor 2?

Answer:
It's unambiguously 3 and the last write from Processor 1 is the last write.

Definition: Cache Coherence

Two executions:



For any execution (beyond the two shown) a memory system is coherent if:

- Memory operations form **one *serial order*** with respect to the ***same*** memory location
- Memory operations from each thread respect ***program order***
- The value returned by a read is the value of the latest write in the ***serial order***

Why Coherence is Important!

Assume A=0, initially

P1		**P2**	
A=1	$W_1(A)=1$	..=A	$R_{21}(A)$
A=2	$W_1(A)=2$	..=A	$R_{22}(A)$

Programmer expectation: ..

If first read from P2 returns a value X, second read must return a value >=X

Examples of **correct** (coherent) interleavings:

$W_1(A)=1 \rightarrow R_{21}(A) \rightarrow W_1(A)=2 \rightarrow R_{22}(A)$

$R_{21}(A) \rightarrow W_1(A)=1 \rightarrow W_1(A)=2 \rightarrow R_{22}(A)$

Examples of **incorrect** (incoherent) interleavings:

$W_1(A)=2 \rightarrow R_{21}(A) \rightarrow W_1(A)=1 \rightarrow R_{22}(A)$

$W_1(A)=1 \rightarrow R_{22}(A) \rightarrow W_1(A)=2 \rightarrow R_{21}(A)$

Assume A=0, initially

P1		**P2**	
A=1	$W_1(A)=1$	..=A	$R_{21}(A)$
A=2	$W_1(A)=2$	..=A	$R_{22}(A)$

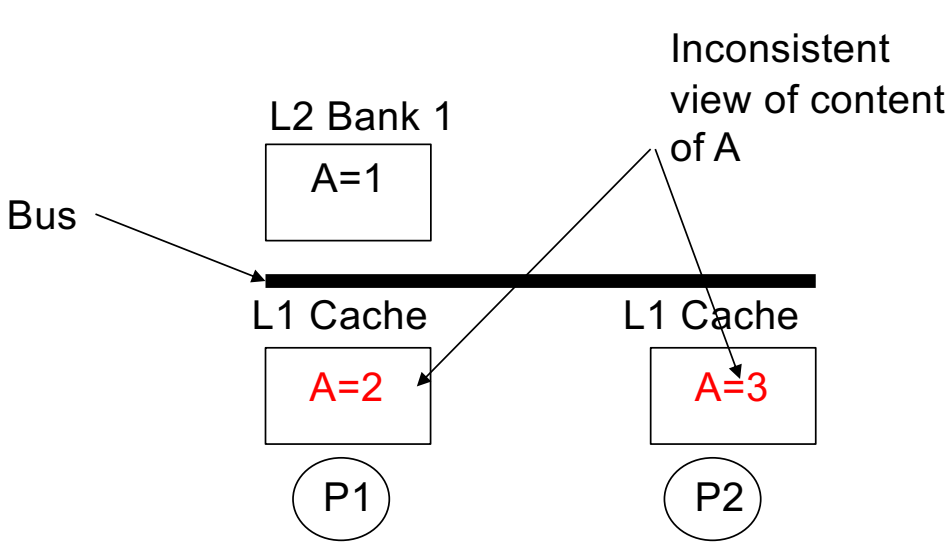
Question:
List all correct serial orders of the program and what R_{21} and R_{22} return in each case.

Answer:

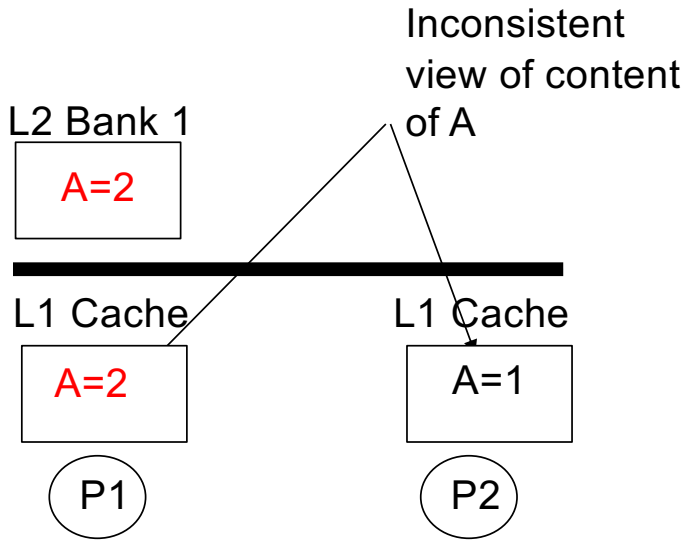
					$R_{21}(A)$	$R_{22}(A)$
S1	$R_{21}(A)$	$R_{22}(A)$	$W_1(A)=1$	$W_1(A)=2$	0	0
S2	$R_{21}(A)$	$W_1(A)=1$	$R_{22}(A)$	$W_1(A)=2$	0	1
S3	$R_{21}(A)$	$W_1(A)=1$	$W_1(A)=2$	$R_{22}(A)$	0	2
S4	$W_1(A)=1$	$R_{21}(A)$	$R_{22}(A)$	$W_1(A)=2$	1	1
S5	$W_1(A)=1$	$R_{21}(A)$	$W_1(A)=2$	$R_{22}(A)$	1	2
S6	$W_1(A)=1$	$W_1(A)=2$	$R_{21}(A)$	$R_{22}(A)$	2	2

Snoopy Cache
Coherence Protocols

The Cache Coherence Problem

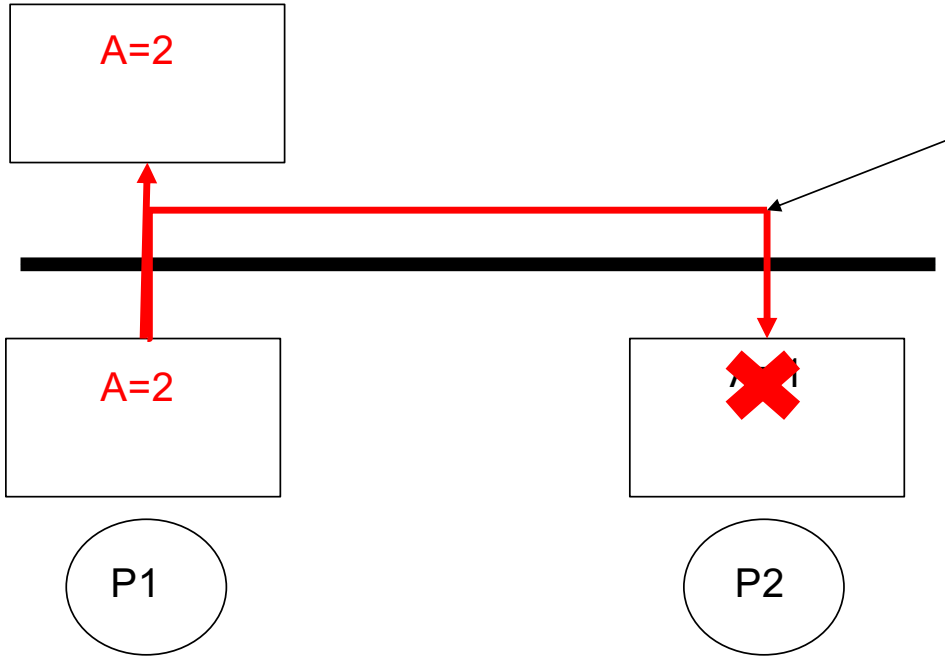


Write-back caches



Write-through caches

A Simple Snoopy Cache Protocol



- Bus acts as serialization point
- Write atomicity is maintained

Write-through caches

Implementing the Simple Cache Protocol

Processor-side requests:
- Processor read – PrRd
- Processor write – PrWr

Bus-side requests:
- Bus read – BusRd
- Bus read exclusive (inval.) - BusRdX
- Bus write (inval.) – BusWr

Cache states per block:
- Valid – V
- InValid – I
